ABSTRACT

One of the most common urological diseases in older men is benign prostatic hyperplasia. The prevalence of this disease increases significantly with age, so the incidence of BPH is 60% by the age of 60, and up to 80% by the age of 80. The aim of the study was to evaluate the efficacy and safety of EPA in the treatment of benign prostatic hyperplasia. Research results have shown that embolization of prostatic arteries is an effective minimally invasive method of treating benign prostatic hyperplasia.

Keywords: prostate gland, benign hyperplasia, prostatic artery embolization.
